### Introduction to R

#### Nikolina Pleić

mag.math.
University of Split
School of Medicine
Department of Biology and Human Genetics

October 2022

### Starting R console

- First, we will create a desktop folder to store our data, example name:
   Intro to R
- Search for R in your Windows app searcher
- $\bullet$  From the console go to File  $\to$  Change dir  $\to$  set to the created folder

# Using R console as a calculator

### Operators:

- Addition: +
- Subtraction: —
- Multiplication: \*
- Division: /
- etc.

You can type R commands in the R console which will be processed and their results output:

```
2+2
## [1] 4
14/7
## [1] 2
```

## Adding comments to the code

- tell R to ignore a part of your program
- R interprets anything after a # as a comment
- commenting your code can help other people read your program
- it can help you understand the code when you go back to an old script

```
a<-25
b<-sqrt(a)
b
## [1] 5
#b is the square root of a</pre>
```

### Data types

In programming and in R, data types are the classifications we give to different kinds of information. We will explore the following R data types:

- Numeric: any number (with or without a decimal point)
- Character (also known as string): any sequence of characters from your keyboard surrounded by quotes
- Logical: only two values: TRUE or FALSE. You can think of them as "yes" or "no" answers to a question
- Vectors: a list of data of the same type
- NA: missing value

# Example data types

```
class(6)
## [1] "numeric"
class('Brain-Gut')
## [1] "character"
class('6')
## [1] "character"
class(TRUE)
## [1] "logical"
class(NA)
## [1] "logical"
```

### Assigning variables

The most basic concept in (statistical) programming is called a variable. A variable lets you store a value or a function which you can later easily access by typing the variable name.

```
#We use the assignment operator, an arrow sign (<-) made
#with a carat and a dash
var1<-100
var1
## [1] 100
var2<-'brain'
var2
## [1] "brain"</pre>
```

### Important things to note

Variable names can't have:

- spaces
- symbols (other than underscore \_ )
- can't begin with numbers, but can have number after the first letter

```
#Example
1-my_variable6<-6
## Error in 1 - my_variable6 <- 6: target of assignment
expands to non-language object

my_variable6<-6
my_variable6
## [1] 6</pre>
```

### Important things to note

Each reassignment updates the variable value:

```
message<-'Hello world!'
print(message)
## [1] "Hello world!"
message <- 'Hello Zagreb!'
print(message)
## [1] "Hello Zagreb!"
#If we don't want to overwrite our variable:
message<-'Hello world!'
message2<-'Hello Zagreb!'
print(message)
   [1] "Hello world!"
```

### Vectors

A list-like structure containing items of the same data type

```
croatian_cities<-c('Zagreb','Split','Rijeka')
croatian_cities
## [1] "Zagreb" "Split" "Rijeka"</pre>
```

Basically, we list the strings and wrap them with c(). Try to create a character vector that contains your address, for example:

```
address<-c('Soltanska 2','21000 Split', 'Croatia')
address
## [1] "Soltanska 2" "21000 Split" "Croatia"
```

Nikolina Pleić Introduction to R 10 / 26

### **Vectors**

#### Operations with vectors:

```
typeof(address)
## [1] "character"
#If we want to get the postal code and the city:
address[2]
## [1] "21000 Split"
length(address)
## [1] 3
```

## Importing packages

Even though base R is very powerful, R packages can make your life easier. A package is a bundle of code that makes performing tasks easier.

Let's import one of the most popular packages: dplyr. Dplyr is a package for cleaning, processing, and organizing data.

1.To install (you do this only once): install.packages('dplyr')

```
#2. To import:
library(dplyr)

##

## Attaching package: 'dplyr'

## The following objects are masked from 'package:stats':

##

## filter, lag

## The following objects are masked from 'package:base':

##

## intersect, setdiff, setequal, union
```

- A data frame in R is an object that stores data in a tabular form, with rows and columns
- Can be created in R, but is most often imported from an Excel spreadsheet
- each column has a name and stores values for one variable
- tibble = data frame

We will now read an excel spreadsheet of biomedical data into R. The data consist of 19 variables on 403 subjects from 1046 subjects who were interviewed in a study to understand the prevalence of obesity, diabetes, and other cardiovascular risk factors in central Virginia for African Americans.

Source: https://hbiostat.org/data/

You can download the data into your created folder from the workshop's

repository at: https://github.com/npleic/BrainGut-Intro-to-R

First, we need a new package: install.packages("readxl")

```
#Since we have set the working directoy to be
#our newly created folder,
#we can load the data downloaded into it.
library(readxl)
data<-read_excel("diabetes_data.xlsx")</pre>
```

Nikolina Pleić Introduction to R 15 / 26

```
#You want to get an understanding of what the data looks like
#Get a preview of rows and columns

```

### Selecting columns

• select() returns a new data frame containing only the desired columns

```
#Let's say we only want to keep age and gender

#It's recommended to keep the ID column

data_age_gender<-select(data, ID, age, gender)

str(data_age_gender)

## tibble [403 x 3] (S3: tbl_df/tbl/data.frame)

## $ ID : num [1:403] 1000 1001 1002 1003 1005 ...

## $ age : num [1:403] 46 29 58 67 64 34 30 37 45 55 ...

## $ gender: chr [1:403] "female" "female" "female" "male" .
```

Nikolina Pleić Introduction to R 19 / 26

## **Excluding columns**

select() also lets us exclude specific columns

```
#Let's say we don't need the variable location
data_without_location<-select(data, -location)</pre>
str(data without location)
  tibble [403 x 11] (S3: tbl_df/tbl/data.frame)
   $ ID
                             : num [1:403] 1000 1001 1002 1003 1005 ...
##
   $ age
                             : num [1:403] 46 29 58 67 64 34 30 37 45 55 ...
   $ gender
                             : chr [1:403] "female" "female" "female" "male" ...
##
   $ height
                             : num [1:403] 62 64 61 67 68 71 69 59 69 63 ...
   $ weight

Nikolina Pleić Introduction to R 21 / 26

## Descriptive statistics

```
#Let's say we want to know the number of male/female participants
table(data$gender)
##
## female male
     234 169
##
#Further, we want to know the average age
summary(data$age) #we're looking at the mean value
    Min. 1st Qu. Median Mean 3rd Qu. Max.
##
##
    19.00 34.00 45.00 46.85 60.00 92.00
#Last, we want to know the median height
summary(data$height)
    Min. 1st Qu. Median Mean 3rd Qu. Max. NA's
    52.00 63.00 66.00 66.02 69.00 76.00
##
```

## Descriptive statistics

```
#Let's inspect variable cholesterol
#We want to know the average cholesterol level
summary(data$cholesterol)
## Min. 1st Qu. Median Mean 3rd Qu. Max. NA's
## 78.0 179.0 204.0 207.8 230.0 443.0
#Let's say we want to inspect cholesterol levels stratified by gender
by(data$cholesterol, data$gender, summary)
## data$gender: female
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 118.0 179.0 204.5 208.4 230.5 443.0
## data$gender: male
## Min. 1st Qu. Median Mean 3rd Qu. Max. NA's
## 78 179
                   204 207 230 404
```

## Exercise - Descriptive statistics

You will now inspect the famous *mtcars* dataset. The data was extracted from the 1974 Motor Trend US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).

Data can be used by calling 'mtcars' in the console. Perform the following tasks:

- 1 Explore the dataset. How many rows and columns are there?
- @ Get the summary statistics of cars' weights.
- Inspect the fuel consumption (Miles/(US) gallon 'mpg') stratified by the number of cylinders 'cyl'.
- From the mtcars data, create a new data frame without the horsepower (hp) and number of gears (gear).

### Exercise - Descriptive statistics

#### Solution:

```
#1.
str(mtcars) #there are 32 rows and 11 columns
#2.
summary(mtcars$wt)
#3.
by(mtcars$mpg,mtcars$cyl,summary)
#4.
library('dplyr')
data_new<-select(mtcars, -c(hp,gear))
str(data_new)</pre>
```

```
print('The End')
## [1] "The End"
```
